CHAPTER 1

INTRODUCTION

This report presents population projections for Nebraska, its planning regions, and its counties at five-year intervals to the year 2020. The state projections were made using a cohort-survival method, and the state totals were allocated to counties using ratio methods. Three projection series -- low, medium, and high -- are included in the report.

This set of projections follows two previous sets of projections, Nebraska Population Projections and Nebraska Population Projections II.[1] Since the completion of those reports, the 1980 census has been concluded and additional, up-to-date data are now available which may alter some of the assumptions used earlier.

As is the case in all projections, population projections represent mathematical extrapolations of future events based on certain underlying assumptions. Population projections are correct by definition because they indicate the population that would result if the base population is correct and if the underlying assumptions turn out to be correct. These assumptions, in turn, are based on past trends in Nebraska and the nation and on an assessment of the likelihood of future changes in these

---

[1]Vernon Renshaw, Nebraska Population Projections, Bureau of Business Research, University of Nebraska-Lincoln and Center for Applied Urban Research, University of Nebraska at Omaha, September 1973; and Vicki Stepp, Nebraska Population Projections II, Nebraska Economic and Business Report Number 14, Bureau of Business Research, University of Nebraska-Lincoln, July 1976.

trends. Thus, an evaluation of the assumptions is important in assessing the accuracy of the projections.

The population projections presented in this report are based on the general assumption that there will be no major catastrophe which would drastically alter the major underlying assumptions for the state. While future levels of the state's population cannot be predicted exactly, changes in trends will have less impact at this level than at the county level.

Unanticipated changes in trends for individual counties will occur which affect their projections. Some of these changes will be minor, but others such as major construction projects, industries entering or leaving an area, or changes in agricultural production will cause dramatic changes in population trends at the county level. These changes cannot be accurately predicted, but they will occur somewhere. For example, in the early 1970s, it was impossible to predict the expansion of the Burlington Northern Railroad in Alliance and the resulting growth in Alliance and Box Butte County. If NPPD decides to build its power plant in Custer County or if the MX missiles are based in Western Nebraska, the projections for these areas will be similarly affected. The projections in this report, therefore, should not be considered immutable, but should be viewed in light of future events.

CHAPTER 2

METHODOLOGY AND ASSUMPTIONS

A general discussion of methods and assumptions is given in this section. The specific equations and a detailed listing of parameter values used in making the projections are presented in Chapter 4.

STATE PROJECTIONS

Projections of the state population by sex and five-year age groups were made using a cohort-survival method. For each five-year period, all five-year age cohorts were survived into the next higher age groups by deducting estimated deaths and adjusting for estimated migration. The initial time period used in the projections was 1980. As an example, the number of persons aged 40-44 for the state in 1985 would be equal to the number of persons 35-39 years old who were living in Nebraska in 1980 less the number of deaths in that age group plus the net difference between those who moved into the state and those in that group who left the state.

The number of persons under five at the end of each projection period was estimated by applying age-specfic birth rates to those female cohorts that are in the childbearing years of 15-44 during the projection period, also adjusting for deaths and migration.

It can be seen then that the cohort-survival method requires three sets of assumptions -- death (survival) rates, birth rates, and migration rates in addition to the number of people in each cohort at the initial period of the projections (1980 in this case). A single set of age- and sex-specific death rates, a single set of birth rate assumptions, and three alternative assumptions about net migration at the state level were used in the projections in this report. The three net migration assumptions result in a high, medium, or low series.

The survival rates used in this report are national rates and are the latest available rates that have been developed by the Bureau of the Census for use in their projections. These rates were projected for five-year cohorts for both males and females in each five year period from 1980 until 2020 and are shown in Table 6 in Chapter 4.

The age-specific fertility rates used here also were derived from rates prepared by the Census Bureau. In their projections the Census Bureau used three series of birth rates -- Series I, II, and III. Series I assumes an ultimate completed fertility rate of 2.7 children per woman, Series II assumes an ultimate rate of 2.1 children (the replacement level), and Series III asumes an ultimate rate of 1.7 children.

State-level birth rates for these series were obtained by calculating the ratios of actual Nebraska birth rates by age for 1975 to 1980 to the national rates. These ratios were assumed

to approach 1.0 linearly by the year 2020. The Nebraska rates used in the projections can be found in Chapter 4 in Table 7.

For the purposes of the projections in this report, only Series II was used. The choice of the medium series is necessarily subjective, but as Table 1 shows, the evidence is strong that Nebraska has been characterized by birth rates close to the long-term replacement level of 2.1 children per woman.[1] In 1970 the total fertility rate was 2.5 children, by 1975 it had fallen to 1.9 children, but in 1980 it had risen to somewhat less than 2.1 children. The medium series assumes that the fertility rate will continue increasing during the 1980s until it reaches 2.2 in 1990, then remain at that level until 2010 when it begins to drop to its ultimate level of 2.1 children per woman.

The most important factor which will affect Nebraska's future population is the migration rate. Other factors will have impacts, but not nearly to the extent as migration. At the state level, three net-migration assumptions are used which result in the three series of projections -- high, medium, and low. The three net migration figures use the basic five- year net migration rates of: 1) no net migration during the 1980s,

one-half percent inmigration during the 1990s, and one percent inmigration for the remaining 20 years; 2) one percent outmigration during the 1980s, one-half percent outmigration during the 1990s, and no net migration during the remaining years; and 3) two percent outmigration during the 1980s, one and one-half percent outmigration during the 1990s, and one percent outmigration during the remaining years. The choice of these migration assumptions was based on evidence that Nebraska has been approaching a position of little or no net migration (see Table 2). There is no reason to suspect these levels will be maintained in the future, but there is currently little evidence to suggest that there will be any large-scale movement of people into or out of the state in the near future.

TABLE 2

NET MIGRATION FOR NEBRASKA: 1940-1980

Period	Net Migration	Migration Rate
1940-1950	-135,000	-10.2

1970-1980	-13,000	-0.9

Source: Compiled by the Bureau of Business Research using the vital-statistics method and data from the U.S. Bureau of the Census and Nebraska Department of Health.

In addition to assuming specific overall migration rates for the state, Table 3 provides evidence which suggests that migration rates differ substantially by age. The highest rates can typically be found in the 20 to 29 age categories, with the rates of both younger and older age groups progressively diminishing. This migration of young adults can have an additional impact on an area since these are the ages of prime fertility. Because of this, the loss or gain of young adults will have an impact on the number of births.

It is important to note that these rates by age are only estimates based on standard estimating techniques and are not available directly from 1980 census results. The apparent immigration of persons 65 and older between 1970 to 1980 is more than likely a statistical aberration because of the estimation methods rather than a large movement of older persons into the state. To estimate the migration rates, mid-decade survival rates were used and probably were too low for the last half of the 1970s. The age-specific rates used in the projections can be obtained by referring to Chapter 4, Table 8.

Athough there almost certainly will be year-to-year fluctuations in birth and migration rates, these fluctuations are essentially unpredictable over the long run. Currently, the most likely fertility and migration patterns appear to be the medium series, with slightly more than two children per family and little or no outmigration. Although this selection is

Source: Gladys K. Bowles, Calvin L. Beale, and Everett S. Lee, Net Migration of the Population, 1960-70, by Age, Sex, and Color, Part 2, Nebraska, Table 3; and compiled by Bureau of Business Research using the census-survival ratios method adjusted to the vital-statistics-method estimates and using data from the U.S. Bureau of the Census and Nebraska Department of Health.

arbitrary, it seems to be the most reasonable given the events of the 1970s. The high and low assumptions provide a reasonable range around those medium assumptions. This range, however, does not allow for significant unforeseen developments which would drastically alter migration patterns, births, and survival rates. The methodology and assumptions used in the projections are presented in Chapter 4. Readers are encouraged to review these assumptions and supply their own numbers as they see fit.

COUNTY PROJECTIONS

County projections by sex and age were made using a ratio method to allocate the state projections to counties. There were two major reasons for using an allocation method rather than the cohort-survival method for the counties. The primary reason for using an allocation method is the belief that because trends are less volatile at the state level, a better state projection can be made if the state is treated as a unit rather than being treated as the sum of independent counties. A closely related reason is the fact that because of the large number of small counties in the state, it would be impossible to obtain reliable birth, death, and migration rates at the county level.

Although it may be better to project the state as a unit rather than to project the counties separately, when the county allocations are made, assumptions must be made about the redistribution of the population among the counties within the state.

The assumptions used in making the projections for the counties in this report involved differences in age structures among counties and differences in age-specific migration rates relative to the state.[2]

Generally, there has been a close association between age structure and population changes. Counties losing population typically have a disproportionately large net outmigration of young adults and experience a much smaller outmigration or possibly inmigration of older persons. This loss of young adults further contributes to population decline by resulting in fewer births and a lower natural increase or possibly natural decline in the counties' populations. Growing counties, on the other hand, are usually characterized by a relatively greater amount of net inmigration of young adults and a much slower net inmigration or possibly outmigration of older adults. For counties with large college populations this pattern is even more pronounced.

County-level projections using a ratio allocation technique start by computing the fraction that each county constitutes of the state's population in each age-sex cohort for the base

---

[2]For total migration rates of counties between 1970 and 1980 with comparisons to previous census periods, see Lynn Nejezchleb, "Migration Trends and Patterns in Nebraska," Business in Nebraska 60, No. 32, Bureau of Business Research, University of Nebraska-Lincoln, June 1981. For additional references see Jerome A. Deichert, Shelley M. Novick, and Anne Stommes Ralston, Migration Patterns of Young Adults in Nebraska, Bureau of Business Research, University of Nebraska-Lincoln, October 1978.

period. For each projection period, these ratios are then modified by using age-specific adjustment factors for each county. These factors primarily were developed by preparing migration rates for each age group relative to the state's rate. For example, the fraction of 10-14 year olds in a county should equal the fraction of 5-9 year olds who were there five years earlier. The adjustment factor would then be applied to this ratio to allow for migration. (For a more detailed discussion see Chapter 4.)

The age-specific migration rates were assumed to remain constant for all projection periods for each county group. Even though some counties had the same adjustment factors, it does not imply that the projected population change will be the same for all counties. The beginning age structure of a county's population also will affect the size of population change. The map in the following chapter shows which counties are projected to grow and which are expected to decline between 1980 and 1990.

CHAPTER 3

FEATURES OF THE PROJECTIONS

STATE PROJECTIONS

In 1990, Nebraska's population is projected to be 1,660,772 persons (based on the medium series). This represents an increase of 5.8 percent from 1980 census figures and compares to a 5.7 percent increase during the previous decade. Between 1990 and 2000, the state is projected to grow to 1,735,240 persons, an additional increase of 4.5 percent. The population projections for the state can be found on pages 39 to 41.

The rates of growth vary depending on the projection series used. Using the low series, the state should increase in population by 3.5 percent between 1980 and 1990 and 2.1 percent between 1990 and 2000. The rates for the high series are 8.2 percent and 6.9 percent, respectively.

Figure 1 and Table 4 display the levels of population for Nebraska since 1930 with projections to 2020 for all three series. As can be seen from the medium series, the population of the state is expected to grow at a faster rate for the forty-year period after 1980 than during the forty years prior to 1980. This primarily reflects the stabilization of migration rates mentioned in an earlier section. Between 1940 and 1980, the state grew at a total rate of 12.9 percent, but between 1980 and 2020 the growth rate, using the medium series, is 21.0 percent.

FIGURE 1

NEBRASKA POPULATION TRENDS

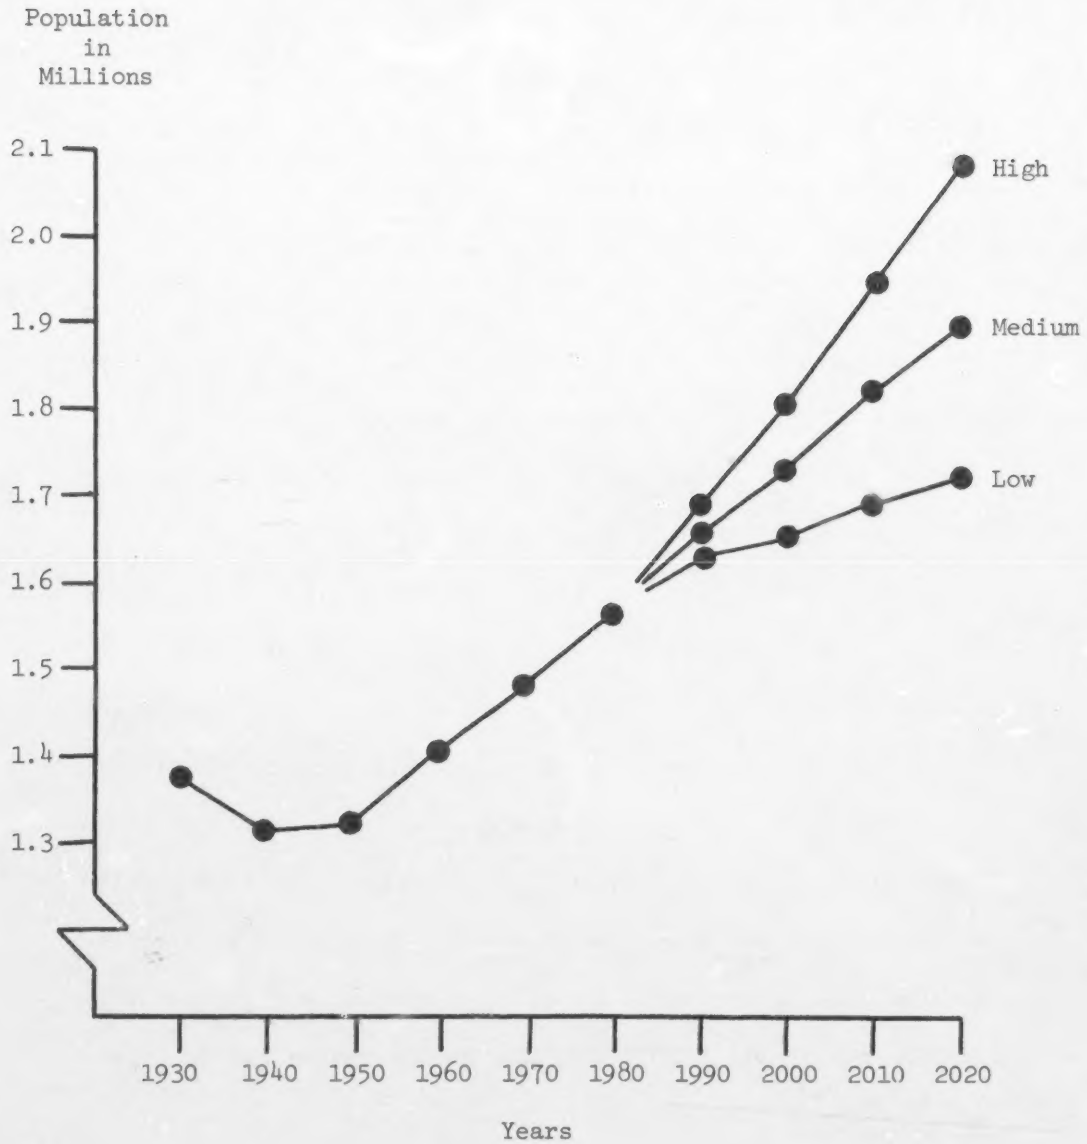

TABLE 4

NEBRASKA POPULATION TRENDS

Year		Population	Percentage Change from Previous Period
1930		1,377,963	
1940		1,315,834	-4.5
1950		1,325,510	0.7
1960		1,411,330	6.7
1970		1,485,333	5.2
1980		1,569,825	5.7
	Low	1,624,007	3.5
1990	Medium	1,660,772	5.8
	High	1,698,041	8.2
	Low	1,658,158	2.1
2000	Medium	1,735,240	4.5
	High	1,815,269	6.9
	Low	1,697,718	2.4
2010	Medium	1,819,736	4.9
	High	1,949,532	7.4
	Low	1,728,755	1.8
2020	Medium	1,899,706	4.4
	High	2,086,130	7.0

Based on the medium series, the age groups which are expected to increase between 1980 and 1990 are 0-9, 25-49, and 60+. The most rapid growth will occur in the group 30-39 years, as this cohort, born during the 1950s, ages ten more years and continues to dominate the Nebraska age structure. One result of this relatively large group of young adults is that the number of births also are expected to increase, leading to a sizable growth in the number of children aged 0 to 9 years in 1990.

The age groups which are expected to decline in size during the 1980s are composed of people born during periods of low birth rates--the 1930s and the 1970s. These age groups which will have fewer members are 10-24 and 50-59.

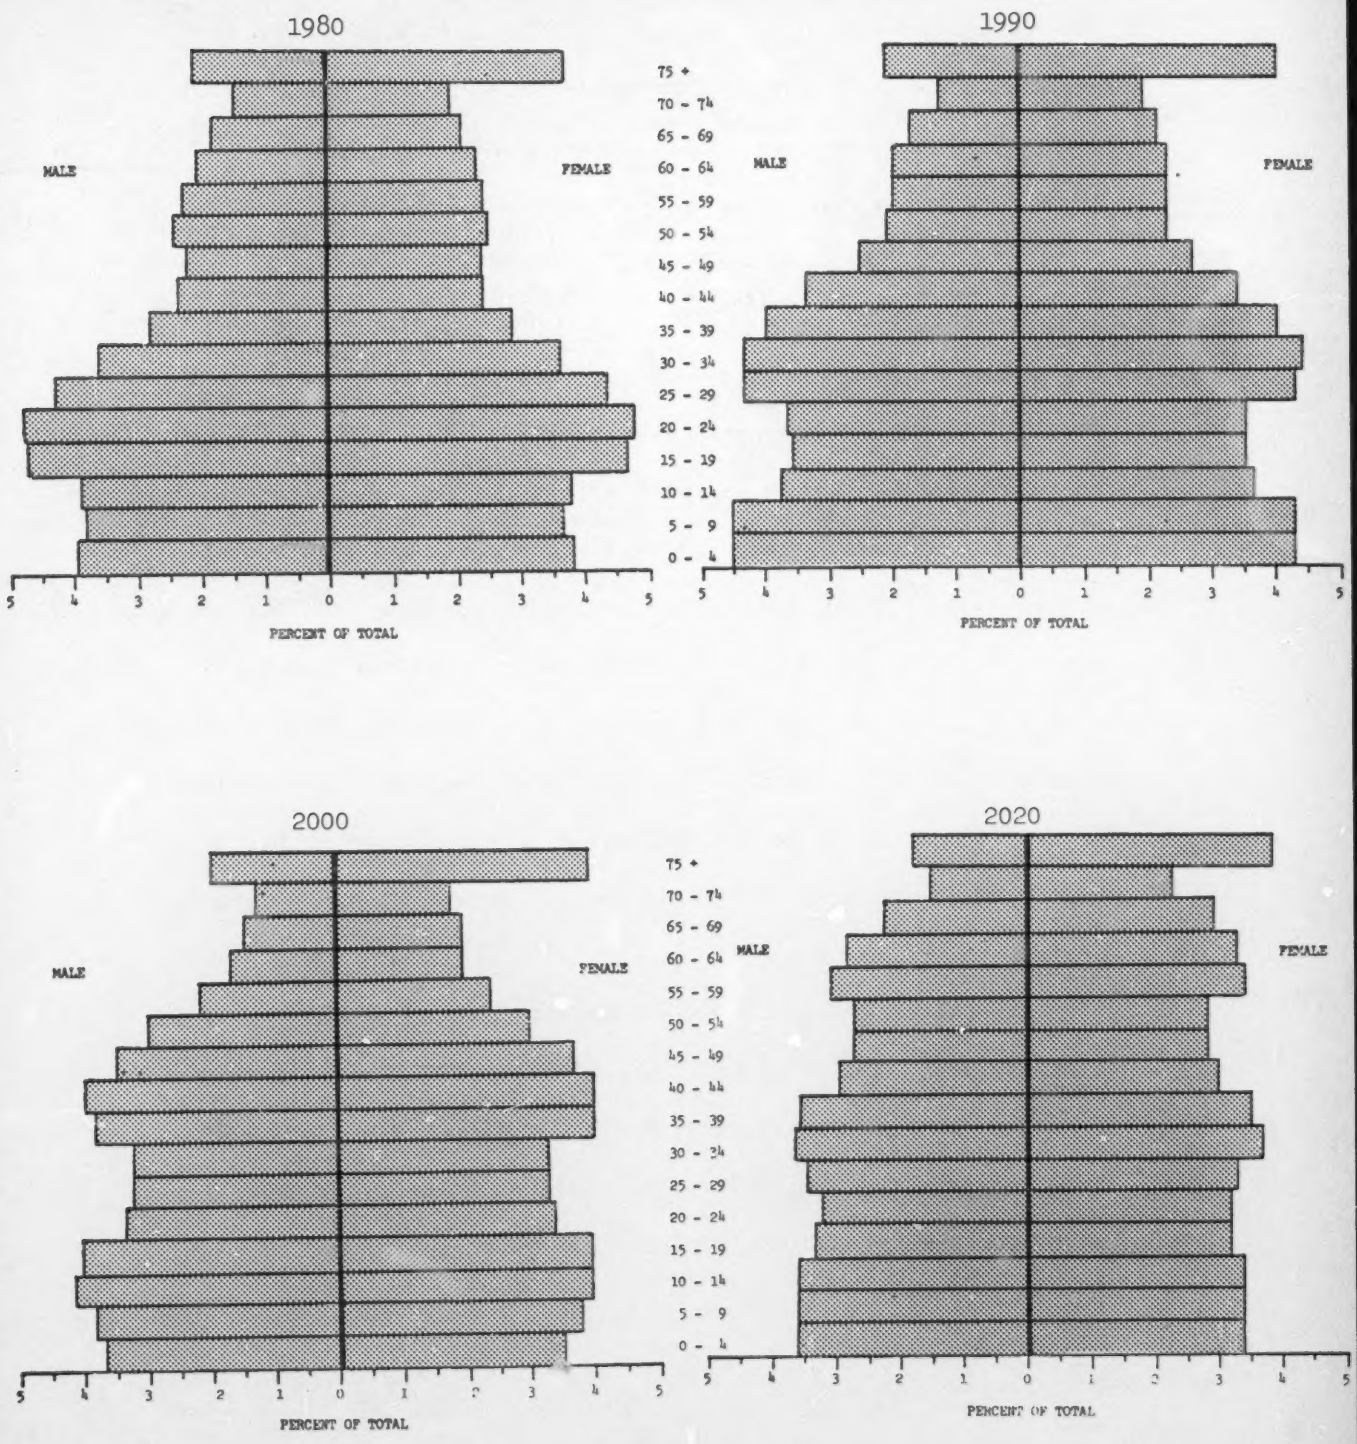
Figure 2 presents a series of age-sex pyramids which show the percentage each five-year age-sex group is of the state total. They are called pyramids because they resemble a pyramid if the youngest age group is placed at the bottom and the oldest at the top. Data represented in Figure 2 are for the years 1980, 1990, 2000, and 2020, and are based on the medium series of projections.

One of the most prominent features of these pyramids is the influence of the large number of persons born during the 1950s. The movement of this cohort can readily be followed as it stands out from the rest of the age groups. In 2020, members of this cohort will be in their sixties. Although no longer the largest cohort, the number of persons sixty years old will be 69.0 percent larger than in 1980. This is more than three times greater

FIGURE 2

DISTRIBUTION OF NEBRASKA'S POPULATION BY AGE AND SEX:

1980 - 2020



than the overall growth rate of 21.0 percent for the state total.

Another significant feature is the gradual disappearance of the pyramid shape. As births decline and life expectancy improves, the difference between the size of the younger and older age groups narrows. To illustrate this fact, the largest group of females will be aged 75 or older in 2020.

EFFECT OF ALTERNATIVE ASSUMPTIONS

The effect of varying migration rates can be seen by looking at the differences in the three series. A change in the net migration rate of one percentage point will result in a change in population slightly larger than that number. If, for example, the five-year migration rate for the state was -5.0 percent rather than -1.0 percent as in the medium series, the state's population would be more than 8 percent lower than previously projected. On the other hand, if the state recorded an inmigration rate of 3.0 percent rather than that assumed in the medium series, the state's population would be more than 8 percent higher than the medium series and 6 percent above the high series.

Changes in fertility rates also can have an impact on population size. Table 5 shows the effect on the state's population for 1990 when different fertility series are used. The data indicate that sensitivity to changes in fertility rates is much less than to changes in migration rates.

TABLE 5

PROJECTIONS FOR 1990 USING THE
THREE FERTILITY ASSUMPIONS

Migration Series	Fertility Series		
	I	II	III
High	1,778,172	1,698,041	1,646,770
Medium	1,738,414	1,660,772	1,611,103
Low	1,699,210	1,624,007	1,575,906

Looking at Table 7, it can be seen that the total fertility rates for the three fertility series are: 2.8 for Series I, 2.2 for Series II, and 1.8 for Series III. When combined with the medium migration series, they result in projections for 1990 of 1,738,414 persons, 1,660,772 persons, and 1,611,103 persons respectively, as shown in Table 5.

Thus, if the total fertility rate was 2.8 births per woman in 1990 rather than the assumed rate of 2.2 births (a 27.3 percent increase), the projected population would be 4.6 percent higher. If the lower total fertility rate of 1.8 births was actually attained in 1990, then the 18.2 percent drop in the fertility rate would result in a 3.0 percent drop in population. In other words, between 1980 and 1990, it would take a 6 percent change in the fertility rate to result in a 1 percent change in population. Table 4 also shows the effect on projected population when the fertility assumptions are combined with the low and high migration assumptions. As can be seen, the range broadens considerably. Combining low fertility with the low

migration series results in a population of 1,575,906, while combining high fertility with the high migration series results in a population of 1,778,172. Since the range in projections is so large as to be meaningless, there is further evidence to indicate the reasonableness of selecting the medium fertility series and allowing only migration rates to vary.

COUNTY PROJECTIONS

Population projections for counties begin on page 69. Many of Nebraska's counties should share in the state's growth, as thirty-eight are projected to grow between 1980 and 1990. For a distribution of these growing counties see Figure 3. Most of the counties which are projected to grow from 1980 to 1990 will continue to grow through 2020 although their growth rates typically are expected to decline.

When reviewing the county-level projections, it is extremely important to remember that local economic events, which are essentially impossible to predict, may significantly alter the projected population figures for individual counties. Furthermore, the reader is reminded that migration is the most important determinant of population change. Migration occurs in response to changing economic conditions, i.e., a new plant in county i or a plantshut down in county j. As noted earlier, there is not an accurate means of predicting these economic events and their impact upon future populations. These projections, therefore, should be considered as basic reference points and should be reviewed as future economic events occur.

CHAPTER 4

PROJECTION EQUATIONS

STATE PROJECTION EQUATIONS

The state projection equations were developed to project population totals for sixteen age groups and eight time periods for both males and females. Totals for each age group are simply the sum of males and females. The sixteen age groups are the five-year age groups from 0-4 to 70-74 and the age group 75 and over. To allow for a better estimate of the 75 and over age group, the estimating equations use both the 75-79 and the 80 and over groups. These groups are then combined to form the 75+ age group. The eight projected time periods are five years apart, beginning in 1985 and ending in 2020.

Except for the youngest (0-4) and oldest (75+) age groups in each sex, the following basic equation is used to project a given five-year age-sex group:

$$POP_{i,j+1,t+1} = POP_{i,j,t} \times SR_{i,j,t} \times M_{i,j,t} \qquad (1)$$

where: POP is the population of a five-year age group,

SR is the proportion of the population in a given five-year age group which is expected to survive over a five-year time interval,

M is the proportion of the population in a given five-year age group which is expected to remain in the state over a five-year time interval,

i is the sex of the population,

j is a given five-year age group, and

t is a given time period.

The equation to determine the proportion of the population which will remain in the state is:

$$M_{i,j,t} = (MR_{i,j,t} \times PP_{i,j,t}) + 1 \qquad (2)$$

where: MR is a migration rate indicating the expected net migration of all persons as a proportion of the total state population, and

PP is an age-phasing pattern indicating the expected net migration rate of a given five-year age group as a fraction of the total rate (MR).

The number of persons 75 and over, the oldest or residual age group, in a given period is estimated by combining the oldest age groups from the previous period by the following:

$$POP_{i,16,t+1} = \sum_{j=15}^{17} (POP_{i,j,t} \times SR_{i,j,t} \times M_{i,j,t}) \qquad (3)$$

For the youngest age group (birth through 4), the population is derived from the estimated births during a given five-year period as follows:

$$POP_{i,1,t+1} = B_{i,\emptyset,t} \times SR_{i,1,t} \times M_{i,1,t} \qquad (4)$$

where: B is the estimated number of births in a five year time interval.

Births are estimated from the number of females in the childbearing cohorts (15-44):

$$B_{i,\emptyset,t} = 5 \sum_{j=4}^{9} \left[\frac{(POP_{F,j,t} \times BR_{F,j,t}) + (POP_{F,j,t+1} \times BR_{F,j,t+1})}{2} \right] \times S_{i,\emptyset,t} \times SR_{i,\emptyset,t} \qquad (5)$$

where: BR is the age-specific birth rate, and

S is the proportion of total births which are either male or female.

35-39	40-44	0.90	80+	85+	0.20

[1]The phasing pattern applies to both sexes and is the same for all time periods.

Source: The primary sources were the previous reports by Renshaw and Stepp. These figures were further adjusted, based on information from the 1980 census and presented in Table 3.

TABLE 9
FIVE-YEAR NET MIGRATION RATES (M)
(in percentages)

Time Period	Series		
	Low	Medium	High
1980-1985	-2.0	-1.0	0.0
1985-1990	-2.0	-1.0	0.0
1990-1995	-1.5	-0.5	+0.5
1995-2000	-1.5	-0.5	+0.5
2000-2005	-1.0	0.0	+1.0
2005-2010	-1.0	0.0	+1.0
2010-2015	-1.0	0.0	+1.0
2015-2020	-1.0	0.0	+1.0

COUNTY PROJECTION EQUATIONS

The county projection equations were developed to project population totals at the county level for the same age groups and time periods that were prepared at the state level. After each round of projections, if there was any discrepancy between the state total for each age-sex group and the value obtained by summing the counties, the county values were further adjusted so that they would sum to the state total.

Except for the youngest and oldest age-sex groups, the basic equation for estimating the county populations is:

$$POP_{i,j+1,k,t+1} = \left[\frac{POP_{i,j,k,t}}{POP_{i,j,S,t}} \right] \times POP_{i,j+1,S,t+1} \times CPP_{i,j,k,t} \qquad (6)$$

where: CPP is an age-phasing pattern which indicates the change in the ratio of the population of a given county to the state as a cohort ages to the next age group,

k is a county's population, and

S is the state total.

The equation for the oldest age group is:

$$POP_{i,16,k,t+1} = \left[\left[\frac{POP_{i,15,k,t}}{POP_{i,15,S,t}}\right] \times POP_{i,16,S,t+1} \times CPP_{i,15,k,t}\right] + \left[\left[\frac{POP_{i,16,k,t}}{POP_{i,16,S,t}}\right] \times POP_{i,16,S,t+1} \times CPP_{i,16,k,t}\right] \quad (7)$$

The population for the youngest age group is derived from a weighted average of the county-state ratios of the female cohorts in childbearing ages:

$$POP_{i,1,k,t+1} = \left[\frac{WF_{k,t}}{WF_{S,t}}\right] \times POP_{i,1,S,t+1} \times CPP_{i,1,k,t} \quad (8)$$

where: WF is the weighted average of females in childbearing ages (15-44) and is calculated by the following:

$$WF_{k,t} = \sum_{j=4}^{9} (POP_{F,j,k,t} \times BR_{j,t}) \quad (9)$$

$$WF_{S,t} = \sum_{k=1}^{93} WF_{k,t} \quad (10)$$

AGE-PHASING PATTERNS FOR COUNTY PROJECTIONS

Since many Nebraska counties have very small populations and have had similar age patterns of migration, counties were combined into groups with similar characteristics to analyze migration. Counties were divided into three broad groups based on age structure and migration and growth patterns. Each broad group was further divided into two or three subgroups depending on variations within the group.

I. Most counties in Nebraska fall into Group I. This group of counties has had consistent and substantial population loss for several decades and a sizable outmigration of persons 15-24 years old. This group is further divided into three subgroups.

A. Counties which also contain a disproportionate share of its population in older age groups:

Antelope, Boone, Boyd, Burt, Butler, Cedar, Cherry, Cheyenne, Clay, Cuming, Custer, Deuel, Dixon, Dundy, Fillmore, Frontier, Furnas, Gage, Garden, Garfield, Gosper, Grant, Greeley, Hitchcock, Holt, Howard, Jefferson, Johnson, Kimball, Knox, Nance, Nuckolls, Otoe, Pawnee, Pierce, Polk, Richardson, Sheridan, Sherman, Thayer, Thurston, Valley, Webster.

B. Counties similar to subgroup A, except that they experienced growth between 1970 and 1980:
Brown, Chase, Franklin, Harlan, Hooker, Morrill, Perkins, Rock.

C. Counties which also experienced a tendency toward net outmigration of people reaching retirement age:
Arthur, Banner, Blaine, Hayes, Keya Paha, Logan, Loup, McPherson, Sioux, Thomas, Wheeler.

II. Counties in Group II generally have recorded growing populations with net inmigration or relatively little net outmigration. There may be some net outmigration in the 15-24 age group, but it is much less than for Group I counties. This group is composed of two subgroups.

A. Counties with some outmigration of 15-24 year olds (much less than Group I) and usually contain a growing city with a population between 2,500 and 10,000:
Box Butte, Colfax, Dawson, Hamilton, Kearney, Keith, Merrick, Phelps, Red Willow, Stanton, York.

B. Counties with little or no outmigration of 15-24 year olds and containing a city larger than 10,000 or adjacent to a metropolitan area:
Cass, Dakota, Dodge, Hall, Lincoln, Madison, Platte, Saline, Saunders, Scotts Bluff, Washington.

BEST AVAILABLE COPY

III. Counties in Group III exhibit a tendency toward sizable inmigration of 15-24 year olds and outmigration of 25-34 year olds. These counties usually contain a college or other institution which attracts young adults. There is only one well-defined subgroup -- those counties in which the three smaller state colleges are located: Dawes, Nemaha, and Wayne. The remaining counties in this group exhibited such dissimilar patterns that they were identified separately. These counties are: Adams, Buffalo, Douglas, Lancaster, Sarpy, and Seward.

[1]The phasing pattern applies to both sexes and is the same for all time periods.

[2]The Group IB phasing pattern is used only for 1985 and 1990. Afterwards counties in this group are assumed to follow the pattern for Group IA.

Source: The major source is from Bureau of Business Research calculations which use the vital-statistics method and data from the 1980 census to compute ten-year migration rates for the age categories in each county grouping. These rates were converted into five-year rates and expressed as a ratio to the state total. These ratios were then compared to the rates published in the Renshaw and Stepp reports.

CHAPTER 5

III. STATE AND PLANNING REGION PROJECTIONS

This section presents high, medium, low projections for the state and its 25 planning regions. The county components of the regions can be found on the map on the following page. These regions follow the guidelines established by the Boundary Redelineation Task Force in 1980. Therefore, they will differ slightly from those used earlier. When these new regions were developed, the two counties which had comprised Region 5 were included with other regions. Because of this, Region 5 no longer exists, but the other regions were not renumbered.

The projections at the state level are by sex and five-year age groups. At the region level, however, the projections are for broader age groups and include a sex breakdown only for the medium series. The state and planning region values may differ slightly from the sum of their individual county components because of rounding after aggregation.
